Script-Controlled ACL – Restrict Record Access Based on Field Value

Phase 3 – Project Design Phase

Team Leader: K. Amirthalakshmi | Team Members: Aisha Sahana S, Aishwarya S, Abirami S

Purpose

• Define how the record, field value, ACL and access decision interact.

High-Level Workflow

• User access request → ServiceNow record → ACL evaluation → field-value check → script condition → allow/restrict decision.

Main Components

• ServiceNow table stores records.

• Controlled field provides the decision value.

• ACL enforces access.

• Script evaluates the field.

• User/tester attempts the protected operation.

Field-Value Flow

• Identify record.

• Read controlled field.

• Compare value with configured rule.

• True → expected access.

• False → expected restriction.

Script-Controlled ACL – Restrict Record Access Based on Field Value

Phase 3 – Project Design Phase – Continued

Logical Design

• The ACL is the enforcement point and the controlled field is the decision input.

Design Rules

• ACL must target the correct table and operation.

• Script must reference the intended field.

• Comparison must match the business condition.

• Logic should remain limited to the requirement.

Design Validation

• Test a record satisfying the condition.

• Test a record failing the condition.

• Review ACL and script when actual behavior differs.

Evidence

• Use the actual ServiceNow configuration and screen recording to capture the design and working flow.

Outcome

• The complete logical flow is defined and ready for implementation.
